

Introduction

The data analyzed in this project is from a larger set taken by Dr P Katz in the late 1990's. A group of children (n=108) were given the measurement at 60 and 72 month mark, however (number) only completed the measure at the 72 month mark.

Hypothesis

H1: Children's SERLI scores will differ between the 60 month mark and the 72 month mark. H2: there will be some interaction between child's awareness of gender stereotypes (p1) and their preferences (p2)
